

# Lab 2: Taking the Temperature of a Cold Brown Dwarf

Ceaser Stringfield, Albert Zhang

The WISE space telescope has measured the flux and wavelengths of light from the nearby brown dwarf WISE 0855-0714 (Luhman et al. 2014)

This data appears to follow Planck's law given by the equation:

$$f(\lambda, T) = \alpha \frac{2hc^2}{\lambda^5} \frac{1}{\exp\left(\frac{hc}{\lambda k_B T}\right) - 1}$$

The shape parameters of such a fit would be a multiplicative factor,  $\alpha$ , and the BD's temperature  $T$ . **Can we fit the data to the Planck function and obtain a posterior distribution for the temperature of WISE 0855-0714?**

We wanted to fit data to a nonlinear model so we used a MCMC algorithm following the Metropolis rule.

The (log) probability was calculated assuming a wide, uninformative uniform prior on  $\log \alpha$  and three different temperature priors

The initial guess bounds were  $[-50, -50]$  for  $\log \alpha$  and  $[0\text{K}, 1024\text{K}]$  for temperature

The jump scales (for Gaussian proposals) were tuned to 0.05 and 3K for  $\log \alpha$  and temperature respectively.

## Model

$$f(\lambda, \alpha, T) = \alpha \frac{2hc^2}{\lambda^5} \frac{1}{\exp\left(\frac{hc}{\lambda k_B T}\right) - 1}$$

## Likelihood

$$\mathcal{L} = \prod_{i=1}^N \frac{1}{\sqrt{2\pi}\sigma_i} e^{-\frac{r_i^2}{2\sigma_i^2}}$$

## Priors

Uniform Prior:  $\mathcal{P}(T) \propto 1$

Log-Uniform Prior:  $\mathcal{P}(T) \propto T^{-1}$

T<sup>4</sup>-Uniform Prior:  $\mathcal{P}(T) \propto T^{-3}$

## METROPOLIS RULE

if  $\mathcal{P}_{\text{trial}} > \mathcal{P}_i$ ,  
accept the jump, so  
 $\theta_{i+1} = \theta_{\text{trial}}$

if  $\mathcal{P}_{\text{trial}} < \mathcal{P}_i$ ,  
accept the jump with  
probability  $\mathcal{P}_{\text{trial}}/\mathcal{P}_i$

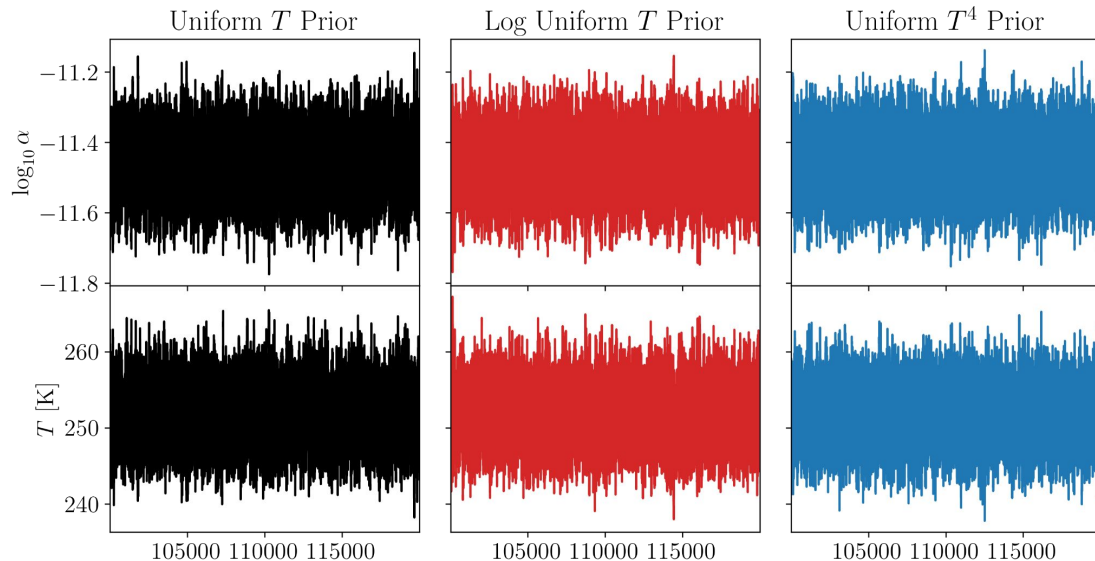

For each of the three  $T$  priors, we ran walkers started on eight different random seeds (same seeds between priors). We obtained 1,048,576 samples from each walker, totaling 8,388,608 per prior.

## Burn-In Check

The first 15,000 steps are plotted here to check the burn-in time. Burn-in was complete by 12,500 steps at most. All three priors are plotted here, but the lines overlap (same seeds).

## Mixing Check

20,000 steps from #100,000 to #120,000 of a walker is displayed here to check for mixing. The sampling appears to be sufficiently mixed for each prior.

# MCMC Results: Posterior Distributions

$$\log_{10} \alpha = -11.459^{+0.077}_{-0.077} \quad -11.458^{+0.078}_{-0.078} \quad -11.456^{+0.077}_{-0.078}$$

— Uniform  $T$  Prior  
— Log Uniform  $T$  Prior  
— Uniform  $T^4$  Prior

**Median  $\pm 1 \sigma$**

Our aggregated results were  $\alpha$  of  $-11.46 \pm 0.08$  and a brown dwarf temperature of  $251.5\text{K} +3.4\text{K}/-3.3\text{K}$ , close to the upper limit of WISE's results ( $225\text{K}-260\text{K}$ ).

$\log \alpha$  and  $T$  are highly correlated. Our fit parameters are not independent. Makes sense referring to Planck equation (for small changes, increasing alpha and decreasing  $T$  have similar effect on flux).

$$T \text{ [K]} = 251.588^{+3.415}_{-3.323} \quad 251.537^{+3.415}_{-3.327} \quad 251.443^{+3.421}_{-3.312}$$

Changing the prior on  $T$  only very slightly alters the posterior distribution. Expect log-uniform and fourth-power-uniform to favor lower values of  $T$ , but our choice of prior is barely noticeable when compared to the width of the posterior
